Monitors

Monitors (I)

- Monitor is a programming language construct that supports controlled access to shared data
 - Synchronization code added by compiler, enforced at runtime
 - Allows the safe sharing of an abstract data type among concurrent processes
- A monitor is a software module that encapsulates:
 - Shared data structures
 - _____ that operate on the shared data
 - Synchronization between concurrent processes that invoke those procedures
- Monitor protects the data from unstructured access
 - Guarantees only access data through procedures, hence in legitimate ways

Monitors (2)

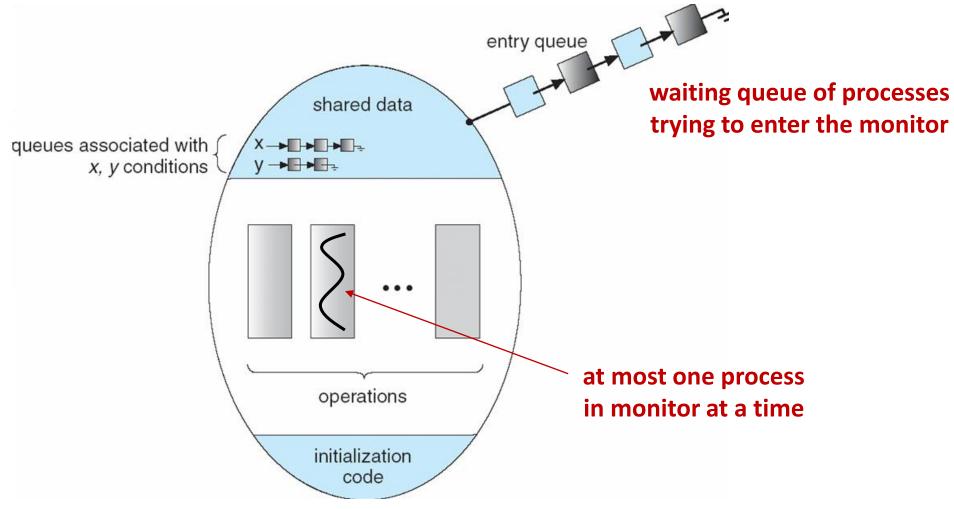

Mutual exclusion

- Only one process can be executing inside at any time
 - Thus, synchronization implicitly associated with monitor
- If a second process tries to enter a monitor procedure, it blocks until the first has left the monitor
 - More restrictive than semaphores, but easier to use most of the time

Condition variables

- Once inside, a process may discover it can't continue, and may wish to sleep, or allow some other waiting process to continue
- Condition variables are provided within monitor
 - Processes can wait or signal others to continue
 - Can only be accessed from inside monitor

Monitors (3)

Condition Variables

Provide a mechanism to wait for events (a "rendezvous point")

- wait(c)
 - Release monitor lock, so somebody else can get in
 - Wait for somebody else to signal condition
 - Thus, condition variables have wait queues
- signal(c)
 - Wake up at most one waiting process
 - If no waiting processes, signal is lost
 - This is different from semaphores: no history!
- broadcast(c)
 - Wake up all waiting processes

Bounded Buffer with Monitors

```
Monitor bounded buffer {
  buffer resources[N];
   condition not_full, not_empty;
  procedure add entry(resource x) {
       while (array "resources" is full)
           wait(not full);
       add "x" to array "resources";
       signal(not empty);
   procedure remove entry(resource *x) {
       while (array "resources" is empty)
           wait(not empty);
       *x = get resource from array "resources"
       signal(not full);
```

Monitors Semantics

Hoare monitors

- signal(c) immediately switches from the caller to a waiting thread, blocking the caller
 - The condition that the waiter was anticipating is guaranteed to hold when waiter executes
 - Signaler must restore monitor invariants before signaling

Mesa monitors

- signal(c) places a waiter on the ready queue, but signaler continues inside monitor
 - Condition is not necessarily true when waiter runs again
 - Being woken up is only a hint that something has changed
 - Must recheck conditional case

Monitors Semantics: Comparison

Hoare monitors

if (notReady)
wait(c);

Mesa monitors

while (notReady)
 wait(c);

- Mesa monitors easier to use
 - More efficient
 - Fewer switches
 - Directly supports broadcast()
- Hoare monitors leave less to chance
 - When wake up, condition guaranteed to be what you expect

Monitors using Semaphores

monitors

```
Semaphore mutex = 1;
Semaphore next = 0;
int next count = 0;
struct condition {
   Semaphore sem;
   int count;
\} x = \{0, 0\};
procedure F() {
  wait(mutex);
   Body of F
   if (next count)
       signal(next);
   else
       signal(mutex);
```

```
procedure cond wait(x) {
  x.count++;
   if (next count)
       signal(next);
   else
       signal(mutex);
   wait(x.sem);
   x.count--;
procedure cond signal(x) {
   if (x.count) {
       next count++;
       signal(x.sem);
       wait(next);
       next count--;
```

Monitors vs. Semaphores

- Condition variables do not have any ______, but semaphores do
- On a condition variable signal(), if no one is waiting, the signal is a
 no-op
 - If a thread then does wait() on the condition variable, it waits
- On a semaphore signal(), if no one is waiting, the value of the semaphore is increased
 - If a thread then does wait() on the semaphore, the value is decreased and the thread continues
